XXXXXXX  
XX XXX

Dear XXXXX,

**Incident**

**Location:** Mountcastle Crescent, Edinburgh (EH8 7SY)  
**Date:** 18<sup>th</sup> December 2019  
**Time:** 06:00  
**Your Reference:** XX/XXX.X.XX

Please find enclosed a Non-CPR Legal Meteorological Report as requested for this incident. The purpose of this Non-CPR Legal Meteorological Report was to provide some evidence (for reference only) on the meteorological facts as to the most likely meteorological conditions in the above area on the date(s) and time indicated. The meteorological issues addressed included examining meteorological data from professional meteorological stations and remote sensed data. This report cannot be used as evidence in a court of law as this incident has not been fully researched and only shows a snapshot of the daily or hourly data in the incident area. No interpretation, conclusion or statement of truth etc. have been included. If later you require a CPR Legal Meteorological Report (for potential court purposes) for this case, please contact me at the above address.

I've much hope that the information is acceptable and please do not hesitate to call if I can offer further assistance in this or in any other legal case in the future.

Yours sincerely,

**Dr Richard J. Wild** BSc (Hons) PhD CertHE FRGS FRMetS MAE MCSFS  
Chief Meteorologist

### Introduction

#### 1.1 The writer

I am Dr Richard John Wild, Chief Meteorologist at WeatherNet Ltd. My specialist field is in forensic meteorology. My qualifications include a CertHE in Environmental Science with Geographical Science, (obtained June 1992), a BSc (Hons) in Geography (2:1) (obtained June 1994), a City and Guilds certificate in Teaching (stage 1) in further and adult education (obtained July 1997) and a PhD investigating the spatial and temporal analysis of heavy snowfalls across Great Britain between the years 1861-1999 (obtained July 2005). WeatherNet Ltd is a private weather consultant and is solely responsible for the conclusions and opinion expressed in this report. WeatherNet Ltd is an Authorised Data user by agreement with the Meteorological Office, Exeter, and its own private meteorological network

across the United Kingdom. The meteorological data from the Met Office abides by the standards set by the World Meteorological Organisation, based in Geneva as the instruments at these meteorological stations, as well as the stations themselves are constantly checked for reliability.

## 1.2 Summary background of the case

I have been asked to provide a Non-CPR Legal Meteorological Report, as to the probable meteorological conditions in the above area on the date and time indicated. As far as I am aware, I have no connection with any of the parties involved in the incident.

1.3 Report prepared for XXXXX XXX XX XXX

1.4 Your reference XX/XXX.X.XX

1.5 Place of incident Mountcastle Crescent, Edinburgh (EH8 7SY)

1.6 Date of incident 18<sup>th</sup> December 2019

1.7 Time of incident 06:00

## 1.8 The parties involved

I have prepared this meteorological report for and on behalf of XXXXX XXX XX XXX.

## 1.9 Technical terms and explanations

If any technical terms are used within this meteorological report, then the explanatory notes section should be consulted in the appendices for further details.

## 2. The meteorological issues addressed and a statement of instructions

I have prepared this meteorological report for and on behalf of XXXXX XXX XX XXX, contained in their correspondence and instructions dated the 16<sup>th</sup> December 2022. The meteorological issues addressed (if available) included examining meteorological data from professional ground based meteorological stations and remote sensed data. This meteorological report has been produced without the benefit of a site visit or investigation. This meteorological report has been prepared for reference only and cannot be presented in court as evidence.

## 3. Details of ground based meteorological/rainfall stations, Remote Sensed data (UKPP) and Rainfall Radar utilised

To establish what meteorological conditions occurred around the surrounding area at the time of the incident, I investigated which were the closest hourly meteorological stations, UKPP, Rainfall Radar, daily meteorological stations, and daily rainfall stations.

The closest meteorological and rainfall stations to the incident were as follows:

The nearest hourly stations to the incident are Edinburgh Royal Botanic Garden No 2 & Edinburgh Gogarbank

The nearest daily stations to the incident are Edinburgh Royal Botanic Garden No 2 & Edinburgh Gogarbank

These hourly and daily meteorological/rainfall data (manned and automatic weather stations) are the best available in the close locality of the incident area.

To establish, what weather conditions occurred across the incident postcode area itself at the time of the incident, I also investigated UKPP and Rainfall Radar data. Rainfall Radar data was available; however, was not requested to be included in this case.

### Hourly Station Data - Key

Precipitation total for the preceding 60 minutes. 0.05mm is trace and can result from dew

Maximum horizontal distance at which a prominent object or light (at night) can be seen with the unaided eye, measured on the hour

Shade air temperature 1.25m AGL, measured on the hour

Relative humidity measured on the hour

Direction from which the wind is blowing at 10m AGL during the 10 minutes preceding the hour

Mean wind speed at 10m AGL for the 10 minutes preceding the hour

GMT = clock time except during BST when it is 1 hour behind

Sunshine total for the 60 minutes preceding the hour

Proportion of sky obscured by aggregate low, medium and high level cloud

Description of weather during the preceding hour

Highest gust at 10m AGL during the 60 minutes preceding the hour

### Hourly Remotely Sensed Data - Key

Hourly totals calculated using trapezoidal rule on 13, 5 minute values. Includes sleet, snow and hail. The hourly totals displayed here are rounded to 1 decimal place and therefore the daily total may not match the sum of the hourly totals

Maximum horizontal distance at which a prominent object or light (at night) can be seen with the unaided eye, measured on the hour

Proportion of sky obscured by aggregate low, medium and high level cloud

Direction from which the wind is blowing at 10m AGL during the 15 minutes preceding the hour

Data extracted from 2km grid cell centred on this location

Relative humidity measured on the hour

GMT = clock time except during BST when it is 1 hour behind

Shade air temperature 1.25m AGL, measured on the hour

Highest gust at 10m AGL for the 15 minutes preceding the hour

Mean wind speed at 10m AGL for the 15 minutes preceding the hour

### Daily Station Data - Key

**MinT** - Lowest of the 24 on-the-hour shade air temperature values for the 24 hours ending 2400 GMT at 1.25m AGL  
**09-09 MinT** - Min shade air temperature for the 24 hours ending 0900 GMT at 1.25m AGL  
**06-18 MinT** - Min shade air temperature for the 12 hours ending 1800 GMT at 1.25m AGL

**Grass min temperature for:**  
**09-09 Grass** - the 24 hours ending 0900 GMT  
**18-06 Grass** - the 12 hours ending 0600 GMT

**MaxT** - Highest of the 24 on-the-hour shade air temperature values for the 24 hours ending 2400 GMT at 1.25m AGL  
**09-09 MaxT** - Max shade air temperature for the 24 hours commencing 0900 GMT at 1.25m AGL  
**06-18 MaxT** - Max shade air temperature for the 12 hours ending 1800 GMT at 1.25m AGL

**Weather station name, distance (km) and direction (cardinal) from postcode**

**Precipitation total:**  
**Rain** - for the 24 hours ending 2400 GMT  
**09-09 Rain** - for the 24 hours commencing 0900 GMT  
**06-06 Rain** - for the 24 hours ending 0600 GMT

**Sunshine total for the 24 hours ending 2400 GMT**

**Highest of the 24 mean wind speeds recorded in the 10 minutes prior to each hour at 10m AGL**

**Lowest of the 24 max gusts recorded in the 60 minutes prior to each hour at 10m AGL**

**Description of notable weather**

**Direction of the mean wind at the time of max gust, measured at 10m AGL**

**Clock time except during BST when it is 1 hour behind**

## The Author

I am the Chief Meteorologist at WeatherNet Ltd. WeatherNet Ltd is a subsidiary of the Claims Consortium Group. I have been employed by WeatherNet Ltd since the 10<sup>th</sup> July 1997. My qualifications include a CertHE in Environmental Science with Geographical Science (obtained June 1992), BSc (Hons) in Geography (2:1) (obtained June 1994), while in July 1997, I obtained a City and Guilds certificate in Teaching (stage 1) in further and adult education. In July 2005, I obtained a PhD investigating the spatial and temporal analysis of heavy snowfalls across Great Britain between the years 1861-1999.

I am a Fellow of the Royal Meteorological Society (since October 1999), a Member of the National Geographic Society (since January 1993), a former Member of the Association of British Climatologists before it ceased (1995-2009) and a Fellow of the Royal Geographical Society (since January 2005). I have produced thirty research articles about snow/snowfalls/blizzards/weather in general in several academic publications (including the Journal of Meteorology and Weather) and four books since 1995. I have also made numerous talks at universities, had local chats/written quotes for local/national radio, TV, and newspapers. Finally, I have been credited and/or acknowledged to have been on over 270 films and various TV programmes including Speed, Harry Potter and the Deathly Hallows: Part 1/2, Alice Through The Looking Glass 2017 and Star Wars: The Force Awakens.

I am also a staff member of TORRO (Tornado and Storm Research Organisation (based at Oxford Brookes University)). My role is Research Leader and Founder of Heavy Snowfalls which is a part of the Thunderstorm and Severe Weather Division and I have held this post since July 2008.

To date, I have prepared more than 2500 legal meteorological reports since the year 1997 and in the last five years, I have given evidence in court on two occasions (April 2018, and April 2019).

Dr Richard Todd, Chief Meteorologist, has over 25 years of experience and, in association with WeatherNet, is listed as an expert witness on several expert witness websites including [www.justicedirectory.co.uk](http://www.justicedirectory.co.uk), [legalexperts-uk.com](http://legalexperts-uk.com), [www.thelawpages.com](http://www.thelawpages.com), [www.postonline.co.uk](http://www.postonline.co.uk), [roundtablegroup.com](http://roundtablegroup.com), [www.yourexpertwitness.co.uk](http://www.yourexpertwitness.co.uk), [www.witnessdirectory.com](http://www.witnessdirectory.com), [xperta.pro](http://xperta.pro), [www.thesolicitorsgroup.co.uk](http://www.thesolicitorsgroup.co.uk), [www.braininjurygroup.co.uk](http://www.braininjurygroup.co.uk), and [www.localgovernmentlawyer.co.uk](http://www.localgovernmentlawyer.co.uk)

I was (in association with WeatherNet Ltd) vetted by the Expert Witness Directory between January 2005 and October 2017, the Expert Witness Directory of Ireland between October 2010 and November 2016 and the Expert Witness Directory of Scotland between October 2010 and October 2016 before they ceased.

Since September 2010, I have been included on the National Crime Agency (NCA) ([www.nationalcrimeagency.gov.uk](http://www.nationalcrimeagency.gov.uk)).

Dr Richard Wild, Chief Meteorologist was 'trained in the aspects of report writing' in July 2008 and the 'Jackson Reforms' in May 2013 by Bond Solon. All legal weather reports comply with this training. <https://www.bondsolon.com/>

## Explanatory notes

### General

All meteorological ground-based readings presented in this report have been made using acknowledged instrumentation and in accordance with procedures laid down by the World Meteorological Organisation (WMO). All meteorological readings in this report have been subject to careful quality control by WeatherNet Ltd. All times shown is Greenwich Mean Time (GMT) unless otherwise stated. These times will be 1-hour BEHIND clock time for the period late March-late October when British Summer Time (BST) is in operation in the United Kingdom.

### The meteorological instrument enclosure

Most meteorological instruments at ground based meteorological stations are in an enclosure, a flat area of ground approximately 10 metres by 7 metres covered by short grass and surrounded by fencing. The enclosure should be well away from trees or any other large obstructions. The distance to any object should be not less than twice the height of the object, and preferably four times the height.

### Ground based meteorological stations

At most ground based meteorological stations, meteorological observations of the highest integrity are made by professional meteorological observers on a routine hourly basis throughout the 24-hour day, 365 days a year. Many meteorological parameters are monitored by automatic equipment (SAWS, SAMOS, CDL) and during periods when (some) ground based meteorological stations are unmanned, evaluations of certain meteorological parameters (present weather, visibility for example) may go unrecorded. Certain other ground based meteorological stations (i.e., Auxiliary meteorological stations (e.g., Coastguard Stations)) only make routine meteorological observations at certain fixed times of the day - often at 3-hourly intervals. At cooperating Climatological Stations, the meteorological observer normally makes only one routine meteorological observation per day at 09:00 GMT. This meteorological observation represents the past 24 hours' e.g., maximum, and minimum temperatures, rainfall, state of ground, sunshine etc. Not all ground based meteorological stations record all meteorological parameters. They are manned by a large variety of persons and in some cases the meteorological observer is available to monitor certain meteorological elements during the daytime, recording a very brief description in the form of a diary. At rainfall stations only, the previous days' 24-hour daily rainfall reading is taken at 09:00 GMT.

### Significant weather

Significant weather includes details of the occurrence of air and ground (grass) frosts; gales; details of any heavy or continuous rain; fog; freezing rain; hail; sleet; snow; lying snow; thunder, lightning; squalls and tornadoes to occur at the ground based meteorological station in the 24-hours ending midnight. 'None' means that

none of these types of weather occurred. 'X' means that no meteorological observation of weather was made.

## Rainfall

The enemies of rainfall measurement are wind and in-splashing. Wind blows rain drops around a rain gauge and therefore the lower the rim (and therefore the lighter the wind) the better. However, if the rim of the rain gauge is too close to the ground, then in-splashing occurs. As a compromise, the standard rain gauge has its rim 30cm above the ground. The diameter is 5 inches (127mm), and rainfall can be measured to a resolution of 0.1mm. From a tipping bucket rain gauge perspective, this does not provide details of the timing of small amounts of rain. A tip of the rain gauge may be triggered in one hour when most of the rain fell in the previous hour. Rainfall (noted in millimetres and tenths) includes any solid precipitation such as snow or hail which is melted and measured in the same way as rain. There may also be small additions due to deposition of dew, hoarfrost, and rime ice on the collecting surface of the rain gauge. Rainfall amounts of 0.05mm are usually recorded as 'trace'. In some instances with automatic meteorological equipment, precipitation amounts less than 0.2mm (i.e., a few spots) will not be registered. Many rainfall stations in the UK are sited on Water Authority property, at reservoirs, sewage works and pumping stations. Daily rain gauges are normally read just once per day at 09:00 GMT, the recorded value being a single measurement of the rainfall of the previous 24 hours. To convert rainfall in millimetres to inches, multiply by 25.4.

## Intensity of rain

Rain (as opposed to rain showers) falls from dynamically produced stratiform (layered) cloud like stratus and nimbostratus in association with frontal zones. Slight rain is rain of low intensity, which usually consists of scattered large rain drops, or many numerous smaller rain drops. The rate of accumulation in a rain gauge is less than 0.5mm per hour. Moderate rain is rain falling fast enough to form puddles quickly, the down pipes flow freely and to give some spray over hard surfaces. The rate of accumulation in a rain gauge is between 0.5mm and 4.0mm per hour. Heavy rain is sufficiently intense to produce a roaring noise on roofs, forms a misty spray of fine rain droplets by splashing on road surfaces etc. and accumulates in a rain gauge at a rate greater than 4.0mm per hour. Moderate and heavy rain is normally associated with layered cloud of great vertical depth, normally in association with frontal zones, or troughs of low pressure. Drizzle is precipitation where the rain droplet size is very small - true drizzle droplets does not make a splash, or circular waves in a puddle. Drizzle is normally associated with very low cloud of the type stratus, and is often experienced in fog, or hill fog (cloud enveloping high ground). Freezing rain/drizzle is liquid water drops, with an air temperature below the zero Celsius mark (super-cooled water), which freeze on impact with a ground surface whose temperature is also below the zero Celsius mark. This form of precipitation produces a particularly hazardous surface for foot

and wheeled traffic. The ground effects of rain on a surface are determined by its rate of impact. In general terms, isolated periods of rain giving a 'trace' or 0.1mm of rainfall would do little more than dampen the ground, whereas 0.2mm falling in less than an hour would wet the ground, but without any puddle formation or puddles will form only slowly. Small puddles would form on some previously dry metalled surfaces (tarmac/concrete) if 0.5mm falls in a relatively short period - say, one hour. Clearly, the size of puddles at any one location/time is, in part, a product of local natural/artificial drainage characteristics. The above criteria based on the ground effects of rainfall amounts are an approximate guide. The state of ground will depend on the intensity of rainfall and the rate of evaporation. Evaporation is very low in winter but averages about 3mm per day in summer. Rainfall can also be described as continuous (rainfalls of one hour or more without a break), or intermittent (a period of less than one hour, or a longer period of rainfall with noticeable breaks). Intermittent rain should not be confused with rain showers (the cloud type from which the precipitate falls is different). With respect to the classification for showers, which are associated with convective cloud, are often of short duration and are characterised by rapid fluctuations of intensity. As a rule, showers are regarded as slight if the rate of accumulation is <2.0mm/hr, moderate 2.0 to 10.0mm/hr, heavy 10.0 to 50.0mm/hr and violent >50.0mm/hr.

#### Rainfall equivalent

1mm of rain measured in a standard rain gauge is the equivalent of 1mm depth over an area of 1 square metre. 1cm of snow is very roughly equal to 1mm. of rain. The range is from about 0.5 to 1.0 multiplied by the equivalent of rainfall, depending on the water content of the snow.

#### Rainfall radar

The methods of collecting rainfall data from rainfall stations are explained in sections 7.5 and 7.6; however, this section will explain rainfall accumulation from rainfall radar. Rainfall Radar (RADio Detection And Ranging) is an echo-sounding system which uses the same aerial for transmitting a signal and receiving the returned echo. Short pulses of electro-magnetic waves are transmitted in a narrow beam for a short time (typically 2 microseconds). When the beam hits a suitable target, some of the energy is reflected back to the radar, which 'listens' out for it for a much longer period (3300 microseconds in the case of Met Office radars) before transmitting a new pulse. The distance of the target from the transmitter can be worked out from the time taken by a pulse to travel there and back. Corrections must be made to the raw data collected, including amendments for attenuation by intervening rain and range, elimination of ground clutter and the conversion of radar reflectivity to rainfall rate.

Each radar completes a series of scans about a vertical axis between four and eight low elevation angles every 5 minutes (typically between 0.5 and 4.0 degrees, depending on the height of surrounding hills). Each scan gives good, quantitative

data that shows detailed distribution of precipitation intensities (1 and 2 km resolutions) out to a range of about 75 km and useful qualitative data that provides a good overall picture of the extent of precipitation at a national/regional scale (5 km resolution) to 255km.

Disadvantages of rainfall radar:

The radar rainfall display may not fully represent the rainfall observed at the ground due to:

- Permanent echoes (occultation) caused by hills or surface obstacles
- Spurious echoes caused by ships, aircraft, sea waves, or clutter in use on military exercises, technical problems, or interference from other radars
- Radar beam above the cloud at long ranges- difficulties in detecting low level rain clouds.
- Evaporation of rainfall at lower levels beneath the beam giving an over-estimate of the actual rainfall.
- Orographic enhancement of rainfall at low levels- light precipitation generated in layers of medium-level cloud can increase in intensity by coalescing up other small droplets as it falls through moist, cloud layers at low levels.
- Bright Band Radar echoes from both raindrops and snowflakes are calibrated to give correct intensities on the rainfall display. However, at the level where the temperature is near 0°C, melting snowflakes with large, reflective surfaces give strong echoes. These produce a false band of heavier rain, or bright band, on the radar picture.
- Anomalous propagation (anprop) radar beams travel in straight lines through a uniform medium but will be refracted when passing through air of varying density. When a low-level temperature inversion exists, the radar beam is bent downwards and strong echoes are returned from the ground, in a manner akin to the formation of mirages.

Advantages of rainfall radar:

- Detection, instantaneous, and integrated rainfall rates
- Local rainfall estimates over a wide area
- Information in near-real time
- Information in remote land areas and over adjacent seas
- Location of frontal and convective (shower) precipitation
- Monitoring movement and development of precipitation areas
- Short-range forecasts made by extrapolation
- Data can be assimilated into numerical weather prediction models

## Temperature

To convert temperatures in Celsius ( $^{\circ}\text{C}$ ) to Fahrenheit ( $^{\circ}\text{F}$ ), multiply by 9, divide by 5 and then add 32. The main problem in measuring air temperature is shielding thermometers from radiation, mainly short-wave radiation from the sun but also long wave radiation from the ground. Mainly, because of radiation, the air (or dry bulb) temperature varies markedly with height above the ground and the type of surface. Thermometers also need to be kept dry as evaporation produces cooling. The solutions to these problems are resolved by recording the temperature of the air (recorded in degrees and tenths, Celsius) by housing the thermometers in the shade, at a height of 1.25 metres above the ground (normally over short grass, except in a few cities where roof top sites are used) in a louvered white box called a Stevenson Screen. The Stevenson Screen protects the thermometers from radiation and precipitation while the louvres permit ventilation. Air temperature values below zero degrees Celsius are preceded by a minus sign, while recordings are made at each (notional) clock hour. In most modern-day ground based meteorological stations; the thermometers are electrical resistance whereas in older ground based meteorological stations they are in form of liquid-in-glass. Different thermometers are used for recording the maximum and minimum temperature. The highest and lowest air temperature recorded during the previous 24-hour period finalises at 09:00 GMT. The wet bulb temperature records the temperature of a wet surface by means of a piece of muslin wrapped around the bulb of a thermometer and kept moist by capillary action from a reservoir of distilled water. The wet bulb thermometer indicates the 'temperature of evaporation' which is, in normal circumstances, lower than the air (dry bulb) temperature. The difference between the dry bulb and wet bulb temperature is known as the wet bulb depression. From the dry and wet bulb readings, relative humidity and vapour pressure can be obtained. The maximum, minimum and wet bulb thermometers are all housed in the Stevenson Screen as mentioned above. The dew point is the temperature to which air must be cooled before it becomes saturated with water vapour. It is so called because it is also the temperature to which a surface must be cooled before dew will be deposited. With reference to thermometers housed outside the Stevenson screen, the grass minimum temperature is recorded by a thermometer exposed to the air one or two inches above the ground. The bulb is in contact with the tips of the grass blades and refers to the period ending at 09:00 GMT on the date of entry. The concrete minimum temperature, like the grass minimum temperature, is recorded by a thermometer, but in this instance, the bulb is positioned in the centre of and just touching the slab and again refers to the period ending at 09:00 GMT on the date of entry. Finally, soil temperatures are read at 09:00 GMT in the morning at selected weather stations. Bent stem thermometers record the soil temperature at 5cm, 10cm and 20cm under a bare soil surface.

## Sun

The total amount of bright sunshine (hours and tenths) recorded on the date of entry. Measurement of the duration of sunshine refers to so-called 'bright' sunshine. Since different meteorological instruments differ in their response characteristics to solar radiation, this term has lacked precise definition. However, The World Meteorological Organisation decided in 1962 to adopt the Campbell-Stokes Recorder, as used in the British Isles, as the standard meteorological instrument for recording sunshine amount.

## Total cloud

Total cloud amounts are estimated as the fraction, in eighths, of the sky covered by cloud. At manned ground based meteorological stations, this is assessed by human observers. Some ground based automatic meteorological stations make this assessment from cloud recording equipment.

## State of ground

At manned ground based meteorological stations, the state of ground refers to a bare patch of soil about 2m square and described accordingly. The state of ground includes descriptions such as dry, moist, flooded, frozen, glazed, sand, ice, snow, or dust covered.

## Snow

Snow is much more difficult to measure than rain because the snowflakes blow around, rather than into, rain gauges. The snow that does enter the gauge blocks it and prevents the normal operation of the rain gauge. Nevertheless, the aim is to record the amount of water substance that falls as snow. At manned ground based meteorological stations, this is achieved by melting the snow and recording the amount of water as 'mm'. Automatic rain gauges do not work well at temperatures below freezing point. Any solid precipitation that falls collects in the rain gauge and no precipitation is registered. When the temperature rises above freezing, the snow melts and the rain gauge starts registering, even though the current weather may be dry. Daily rainfall amounts are quality controlled to overcome this deficiency and estimates of the correct daily rainfall are made. For hourly rainfall, it is more likely that original and erroneous data remain on the computer archive. There is a close relationship between the intensity of snowfall and visibility. Thus, if it is known that poor visibility is due to falling snow, the intensity of the precipitation can be inferred from the following table.

Visibility	Description of snowfall intensity	Equivalent rainfall intensity
5km	Slight snow	0.2mm/hr
2km	Slight/moderate snow	0.5mm/hr
1km	Moderate snow	1.0mm/hr
250m	Moderate/heavy snow	4.0mm/hr
110m	Heavy snow	10.0mm/hr

Dry snowflakes result in visibilities only about half of those given above. Visibility in wet snow is somewhat better, as wet snowflakes collapse to a smaller volume and become translucent. Blowing snow (most likely when the snow is dry and powdery) gives very low visibilities.

#### Snow depth

At manned ground based meteorological stations, snow depth is measured with a ruler at three different locations and the average is then taken. The area chosen for these measurements should be as close as possible to the rain gauge and not affected by drifting or scoured by the wind. Some automatic ground based meteorological stations measure snow depth using an optical technique.

#### Wind

Wind direction is measured in degrees from north (360 degrees of a circle) and relates to the direction from which the wind is blowing from. The quoted figures represent the wind direction averaged over the hour ending at the time of entry. A direction reported as 0 degrees represents a wind from due north (a northerly wind); 090 degrees is from the east (an easterly wind) etc. Wind speeds are recorded in knots (where 1 knot = 1.1515 mph), and they refer to the average speed (which includes all gusts and all lulls) during the hour ending at the time of entry. The mean wind speed refers to the highest mean wind at 10m above ground in an open level situation measured in the 10 minutes immediately preceding each hour. The maximum gust speed is also recorded in knots; the highest value (even if only of momentary duration) attained during the hour ending at the time of entry. The maximum wind gust refers to the highest 3-5 second gust at 10m above ground level by an anemometer. A gust is a rapid, but momentary increase in the speed of the wind, relative to the mean wind speed at the time. Equally, a lull is a momentary decrease below the mean wind speed. Wind speed generally increases with height according to a power law expression, i.e., Speed at height H = speed recorded at 10 metres x Pow ((Height H in metres/10 metres) p) where the power p takes a value between 0.067 and 0.29 depending upon local terrain roughness and whether it is mean or gust speed under consideration. Beaufort Force = Pow(Pow(("Wind Speed (mph)" / 1.87), 2), 1/3). Beaufort Forces apply only to mean wind speeds and must not be used in reference to gusts.

## Glossary of Meteorological Terms

**AGL** - Height Above Ground Level in metres.

**ASL** - Height Above Sea Level in metres.

**Astronomical dawn and dusk** - Morning astronomical twilight begins (astronomical dawn), and evening astronomical twilight ends (astronomical dusk) when the geometric centre of the Sun reaches 18° below the horizon. In the period of astronomical twilight (when the sun is between 12° and 18° below the horizon), away from urban light pollution, moonlight, auroras and other sources of light, the sky is darker enough for nearly all astronomical observations. Amateurs can easily make observations of point sources such as stars both during and after astronomical twilight in the evening and both before and during astronomical twilight in the morning. Some critical observations, however, such as viewing nebulae and galaxies require observations beyond the limit of astronomical twilight. In theory, the faintest stars detectable by the naked eye (those of approximately the sixth magnitude) will become visible in the evening at astronomical dusk and become invisible at astronomical dawn. In certain places, astronomical twilight may be almost indistinguishable from night. In the evening, even when astronomical twilight has yet to end and in the morning when astronomical twilight has already begun, most casual observers would consider the entire sky fully dark.

**Black ice** - is a thin coating of ice on a ground surface, formed when moisture from either natural or unnatural sources (for example, rain, freezing rain or drizzle, surface run-off, etc.) becomes present on exposed objects with a surface temperature below or at freezing (0°C). It is near transparent due to the fact it is only a thin accumulation of ice, making it much harder to see in comparison to snow, frozen slush, or thicker ice layers. The 'black' term comes from the fact that when the ice or 'glaze' forms on a road surface, the black tarmac underneath can be seen clearly through it presenting a distinct risk of pedestrians and automobiles.

**Civil twilight** - is defined to begin at sunset and ends when the geometric centre of the sun is 6° below the horizon. This is the limit at which twilight illumination is enough, under good weather conditions, for terrestrial objects to be clearly distinguished. At the end of evening civil twilight, the horizon is clearly defined, and the brightest stars are visible under good atmospheric conditions in the absence of moonlight or other illumination.

**Cloud Cover** - The total cloud amount or cloud cover is the fraction of the celestial dome covered by all clouds visible. The assessment of the total amount of cloud, therefore, consists in the weather observer estimating how much of the total apparent area of the sky is covered with cloud. The international unit for reporting the cloud amount is the 'okta' or eighth of the sky, with 0 oktas equating to a clear sky and 8 oktas equating to an overcast sky.

*Cold Front* - A frontal system whose movement is such that the colder air mass is replacing the warmer air mass. The passage of the cold front is marked at the surface by a rise in pressure, a fall of temperature and dewpoint and a veer of wind direction.

*Condensation* - In meteorology, the formation of liquid water from water vapour. Since the capacity of air to hold water in the form of vapour decreases with temperature, cooling of air is the normal method by which first saturation, then condensation, is produced. Such cooling is affected by three main processes:

- (i) the expansion of ascending air,
- (ii) mixing with air at lower temperature,
- (iii) contact with earth's surface at lower temperature.

The water vapour condenses as cloud in (i), as fog or cloud in (ii), and as dew or hoar frost in (iii).

*Dew* - Condensation of water vapour on a surface whose temperature is reduced by radiational cooling to below the dewpoint of the air in contact with it. Of the two recognized processes of dew formation, the more common occurs in conditions of calm (wind at two metres height less than one knot) when water vapour diffuses from the soil upwards to the exposed cooling surface in contact with it (e.g., grass) and there condenses. The second of the processes is one of 'dewfall' when, in conditions of light wind, downward turbulent transfer of water vapour from the atmosphere to the cooling surface occurs.

*Dew-Point* - The dewpoint of a moist air sample is that temperature to which the air must be cooled in order that it shall be saturated with respect to water at its existing pressure and humidity mixing ratio. Dewpoint may be measured indirectly from wet- and dry-bulb temperature readings with the aid of humidity tables, or directly with a 'dewpoint hygrometer'.

*Freezing drizzle, freezing fog, freezing rain* - Supercooled water drops of drizzle (or rain) which freeze on impact with the ground to form glazed frost or, in the case of small droplets which comprise of fog to form rime.

*Freezing-point* - The constant temperature at which the solid and liquid forms of a given pure substance are in equilibrium at standard atmospheric pressure. For pure-water substance the temperature is 0°C and is termed the 'ice-point' or 'freezing-point'. In practice, a cooling liquid may not freeze at the freezing-point due to a pressure variation from standard atmospheric pressure, or the presence of impurities, or the phenomenon supercooling.

*Frost* - Frost occurs when the temperature of the air in contact with the ground or at screen level (about four feet), is below the freezing-point of water ('ground frost' or

'air frost', respectively). The term is also used of the icy deposits which may form on the ground and on objects in such temperature conditions.

*Frost Hollow* - A local hollow-shaped region in which, in suitable conditions, cold air accumulates by night due to a katabatic air flow (see katabatic wind definition). Such regions are subject to a greater incidence of frosts and to more severe frosts, than are the surrounding areas of non-concave shape.

*Funnel cloud* - Is a funnel-shaped cloud of condensed water droplets, associated with a rotating column of wind and extending from the base of a cloud (usually a cumulonimbus or towering cumulus cloud) but not reaching the ground or a water surface. A funnel cloud is usually visible as a cone-shaped or pipe-like protuberance from the main cloud base. Funnel clouds form most frequently in association with supercell thunderstorms. If a funnel cloud touches the ground, it becomes a tornado. Most tornadoes begin as funnel clouds, but many funnel clouds do not make ground contact and so do not become tornadoes.

*Glazed Frost* - A coat of ice, generally smooth and clear, formed by the falling of rain or drizzle (or sleet) on a surface whose temperature is below freezing-point: It may also form due to a sudden onset of rain, moist air following a severe frost, by the condensation and freezing of water on surfaces at temperatures still below freezing-point.

*Grass Minimum Temperature* - The minimum temperature indicated by a thermometer freely exposed in an open situation at night with its bulb in contact with the tips on the grass blades in an area covered with short turf.

*Ground Frost* - The term in forecasts signifies a ground minimum temperature of 0°C (32°F) or below when ice forms on the ground, objects etc., causing water to freeze. Because the ground cools quicker than the air around a metre above, it is possible for a ground frost to occur without an air frost. This, as a general rule of thumb, occurs when the air temperature is  $\leq 3^{\circ}\text{C}$  (39°F) with little or no cloud and light winds. From a layman's perspective this criterion is often shown as a yellow based snowflake on a car dashboard. A slight ground frost is when the ground temperature has fallen to 0°C or slightly below for a few hours, while a moderate frost is where ground temperatures have fallen to -2°C or below and/or for a noticeable longer period of time.

*Gust front* - is a leading edge/boundary (squall line) that separates a cold downdraft (outflow (winds that flow outwards from a thunderstorm)) of an organised line of thunderstorms from warm, humid surface (environmental) air. Its passage at the surface resembles the passage of a cold front. This squall line is marked by upward motion along it and downward motion behind it. It is normally followed by a surge of gusty winds on or near the ground. A gust front is often associated with an

atmospheric pressure rise, wind shift, an air temperature drop and sometime heavy precipitation.

*Hoar/Grass Frost* - This is a series of interlocked ice crystals that develop on surfaces during cold, typically clear nights where the exposed surface is chilled below the dew point of the surrounding air and the surface itself is colder than 0°C. Similarly, where air cooled by ground-level radiation loss travels downhill to form pockets of cold air in depressions, valleys and frost hollows, hoar frost can form even where the air temperature above ground is above freezing.

*Humidity* - This is the term used to describe the amount of water vapour in the air and can indicate the likelihood of precipitation, dew, or fog. A device used to measure humidity is called a hygrometer. At an official weather station, humidity is recorded by a wet bulb and dry bulb thermometer. The difference between the two temperature readings allows the observer to calculate the dew point and the humidity in a percentage form.

*Katabatic wind* - On a 'radiation night' of clear skies and low pressure gradient, terrestrial radiation from the earth's surface causes a layer of cold air to form near the ground, with an associated inversion in temperature. If the ground is sloping, the air close to the ground is colder than air at the same level but at some horizontal distance. Downslope gravitational flow of the colder, denser air beneath the warmer, lighter air results and comprises the 'katabatic wind'.

*Knot* - Unit of measurement of wind speed. 1kt = 1.152mph = 0.514m/s.

*Nautical dawn and dusk* - Morning nautical twilight begins (nautical dawn), and evening nautical twilight ends (nautical dusk) when the geometric centre of the sun reaches 12° below the horizon. Nautical twilight (when the sun is between 6° and 12° below the horizon), artificial lighting must be used to see terrestrial objects clearly. Before nautical dawn and after nautical dusk, sailors cannot navigate via the horizon sea. Under good atmospheric conditions with the absence of other illumination, during nautical twilight, the human eye may distinguish general outlines of ground objects but cannot participate in detailed outdoor operations.

*Occlusion* - A front which develops during the later stages of the life cycle of a frontal depression. The term arises from the associated occluding (shutting off) of the warm air from the earth's surface.

*Okta* - Unit, equal to area of one eighth of the sky, used in specifying cloud amount.

*Sensible and Latent Heat (Hidden Heat)* - In meteorology, latent heat flux is the flux of heat from the Earth's surface to the atmosphere that is associated with evaporation or transpiration of water at the surface and subsequent condensation of

water vapor in the troposphere. It is an important component of Earth's surface energy budget.

*Sleet* - Precipitation of snow and rain together or of snow melting as it falls.

*Squall* - is a sudden, sharp increase in wind speed which is usually associated with active weather, such as rain showers, thunderstorms, or heavy snow. Squalls refer to an increase in the sustained winds over a short time interval, and there may be higher gusts during a squall event. They usually occur in a region of strong mid-level height falls, mid-level tropospheric cooling, which forces strong localised upward motions at the leading edge of the region of cooling, which then enhances local downward motions just in its wake.

*Straight-line winds* - are very strong winds that can produce damage, demonstrating a lack of a rotational damage pattern. Such rotational damage patterns are associated with cyclonic storms including typhoons and tropical cyclones. Straight-line winds are common with the gust front of a thunderstorm or originate with a downburst from a thunderstorm. These events can cause considerable damage, even in the absence of a tornado. The winds can reach 80mph (130km/h) or more and can last for periods of two minutes or longer.

*Synoptic Meteorological Charts* - this is a weather chart that reflects the state of the atmosphere over a geographic area at a certain time based on information gathered from weather stations at surface level. The chart is created by plotting or tracing the values of relevant quantities (including sea level pressure, temperatures, etc.) and show the presence or potential development of weather fronts and systems.

*Thaw* - The transition by melting from snow or ice to water. The term is especially used to indicate the end of a spell of frost, which in the British Isles in winter is generally associated with the displacement of a stagnant or continental air mass by one of maritime origin.

*Tornado* - is a violently rotating column of air that is in contact with both the surface of the earth and a cumulonimbus cloud. Tornadoes come in many shapes and sizes, but they are typically in the form of a visible condensation funnel, whose narrow end touches the earth and is often encircled by a cloud of debris and dust. Most tornadoes have wind speeds less than 110 mph (177km/h), are about 250 feet (76m) across, and travel a few miles before dissipating.

*Trough* - A non-frontal line on a synoptic chart usually associated with an organised band of generally cloudy, showery weather.

*Visibility* - Meteorological visibility is defined as the greatest distance at which a black object of suitable distance can be seen and recognised against the horizon

sky. The simplest determinations of daylight visibility have, for many years, been deduced by how well a series of objects or lights of known distance can be seen from a certain point of a meteorological station. The estimated distance is then noted in the records. More recently, however, automated weather systems including a "forward scatter sensor" have been used, particularly at airports. This instrument produces pulsed flashes of light, some of which is scattered at an angle towards a nearby detector. Visibility is then estimated from the intensity of the scattered light. The sensors report a visibility based on one-minute samples averaged over the past ten minutes leading up to each observation.

*Warm Front* - A frontal system whose movement is such that the warmer air mass is replacing a colder air mass. The passage of a warm front is marked at the surface by a rise in temperature and dewpoint, a veer of wind direction and a steadying of pressure.

## Disclosure

- Any information, advice, recommendations or other contents of the report or other communications have been prepared for the sole use of the client.
- The report may only be disclosed to third parties with prior written consent, to be used only as specified in said consent.
- The report shall not be altered, edited, or modified by third parties.
- You and any associates or subsidiaries shall not be entitled to any amount with respect of loss of profit, loss of data or damage to goodwill or any consequential, incidental, indirect, or special loss as a result of the contents of the report, whether or not the likelihood of such loss or damage was contemplated.
- The client/WeatherNet and/or Dr Richard Wild shall have no liability whatsoever to any third parties in respect of the report.
- You and/or your insurers are not entitled to place any reliance on the report.
- You shall indemnify the client/WeatherNet and/or Dr Richard Wild against all claims by third parties (including affiliates) and resulting liabilities, losses, damages, costs, and expenses (including reasonable external and internal legal costs) arising out of third party use or reliance on the report.
- All intellectual property rights and materials in connection with the report are retained by the client/WeatherNet and/or Dr Richard Wild.
- Except as otherwise permitted you may not disclose to third parties the contents of this agreement or any information provided by or on behalf of the other that you reasonably believe to be treated as confidential and (or proprietary). The client/WeatherNet and/or Dr Richard Wild may however disclose such information to the extent that it: (a) is or becomes public other than as a result of a breach of this agreement, (b) is subsequently received by the recipient from a third party who, to the recipient's knowledge, owes no obligation of confidentiality to the disclosing party with respect of that information, (c) was known to the recipient at the time of disclosure or is thereafter obtained independently, or (d) must be disclosed under applicable legal process or professional regulation;
- You agree that if any request under the Freedom of Information Act 2000 is received (where they are subject to it) for disclosure of information provided by the client, they will promptly notify you of such request prior to any disclosure.
- If circumstances arise such that it is necessary to disclose information to the National Crime Agency, (NCA) for instance, due to the restrictions imposed by law you may be prevented from discussing such matters with you. If this arises the client/WeatherNet and/or Dr Richard Wild shall have no liability to you.
